

What is claimed is:

1. A garbage collecting method for a memory resource in a computer system, comprising:

for each of a plurality of objects in the memory resource, maintaining a reference count based on a number of objects pointing thereto, and maintaining a depth value based on a distance from a global data object; and

identifying, based on the associated reference count and depth value, which of the plurality of objects are to be processed to determine whether or not they are garbage.

2. The method of claim 1, wherein:

for each object, the depth value is maintained by providing a depth field in metadata associated with the object.

3. The method of claim 1, wherein:

a first of the objects is identified to be processed when it is determined that a second of the objects previously pointing thereto is no longer pointing thereto, and the depth value of the second object is one less than the depth value of the first object.

4. The method of claim 3, wherein:

the second object is no longer pointing to the first object because it was destroyed.

5. The method of claim 3, wherein:

the second object is no longer pointing to the first object because it was reset to point to another object.

6. The method of claim 1, wherein:

the distance for each of the plurality of objects is based on a number of objects linking the each of the plurality of objects to the global data object.

7. The method of claim 6, wherein:

the objects processed to determine whether or not they are garbage are processed by a loop detection mechanism for a reference counting garbage collector.

8. The method of claim 1, further comprising:

initializing the depth value of a new object created at runtime to one more than the depth value of an object that points to the new object and links the new object to the global data object.

9. The method of claim 1, wherein

when a particular one of the objects that is processed is determined to be garbage, its associated portion of the memory resource is made available for re-allocation.

10. The method of claim 1, wherein

when a particular one of the objects that is processed is determined to be non-garbage, its depth value, and the depth values of other ones of the objects that are pointed to by the particular object and linked to the global data object thereby, are reset.

11. The method of claim 10, wherein:

the depth values of objects that are pointed to by the other ones of the objects whose depth values are reset, and linked to the global data object thereby, are also reset.

12. The method of claim 10, wherein:

the particular object is determined to be non-garbage when it is accessible to outside objects.

13. The method of claim 1, wherein:

when a new link is created from a first object of the plurality of objects to a second object of the plurality of objects, and the first object has a valid depth value but the second object does not have a valid depth value, the depth value of the second object is initialized to one more than the depth value of the first object.

14. The method of claim 1, further comprising:

initializing a depth value of the global object to any valid depth value.

15. The method of claim 1, further comprising:

initializing depth values of the plurality of objects to a specified value.

16. A computer program product for implementing a garbage collecting method for a memory resource in a computer system, comprising:

computer code devices configured to cause a computer to maintain, for each of a plurality of objects in the memory resource, a reference count based on a number of objects pointing thereto, and maintain a depth value based on a distance from a global data object; and

identify, based on the associated reference count and depth value, which of the plurality of objects are to be processed to determine whether or not they are garbage.

17. A computer system for implementing a garbage collecting method for a memory resource thereof, comprising:

a processor and memory for maintaining, for each of a plurality of objects in the memory resource, a reference count based on a number of objects pointing thereto, and maintaining a depth value based on a distance from a global data object, and for identifying, based on the associated reference count and depth value, which of the plurality of objects are to be processed to determine whether or not they are garbage.
